

# PROBABILITY REVIEW

---

## BAYESIAN STATISTICS FOR ECOLOGISTS

IGB 12. TO 19. NOVEMBER 2018

# A MORE NATURAL WAY TO THINK ABOUT STATISTICS

- ▶ I want to describe some phenomenon

## A MORE NATURAL WAY TO THINK ABOUT STATISTICS

- ▶ I want to describe some phenomenon ("model")

# A MORE NATURAL WAY TO THINK ABOUT STATISTICS

- ▶ I want to describe some phenomenon ("model")
- ▶ I have some general knowledge about the question

## A MORE NATURAL WAY TO THINK ABOUT STATISTICS

- ▶ I want to describe some phenomenon ("model")
- ▶ I have some general ("prior") knowledge about the question

# A MORE NATURAL WAY TO THINK ABOUT STATISTICS

- ▶ I want to describe some phenomenon ("model")
- ▶ I have some general ("prior") knowledge about the question
- ▶ I gather additional knowledge

# A MORE NATURAL WAY TO THINK ABOUT STATISTICS

- ▶ I want to describe some phenomenon ("model")
- ▶ I have some general ("prior") knowledge about the question
- ▶ I gather additional knowledge ("data")

# A MORE NATURAL WAY TO THINK ABOUT STATISTICS

- ▶ I want to describe some phenomenon ("model")
- ▶ I have some general ("prior") knowledge about the question
- ▶ I gather additional knowledge ("data")

What is the probability that my **model is correct** given what I **already know about it** and **what I've learned**?

## STATISTICAL INDEPENDENCE

- ▶ We wish to make a statistical conclusion from some vector of observations  $\mathbf{y}_{1..i}$
- ▶ We assume that the  $y_i$ 's are **i.i.d.**
- ▶ What does this mean?

# STATISTICAL INDEPENDENCE

- ▶ Two events **A** and **B** are independent if the probability of **A** occurring does not depend on whether **B** has occurred, and vice-versa

Total sample space

$\text{pr}(A)$  – marginal probability of A

$\text{pr}(A) + \text{pr}(B) - \text{the probability of either one OR both}$

$A \cap B$  (A and B) – also written  $\text{pr}(A,B)$

# STATISTICAL INDEPENDENCE

- ▶ Two events **A** and **B** are independent if the probability of **A** occurring does not depend on whether **B** has occurred, and vice-versa
- ▶ If **A** and **B** are independent:
  - ▶  $\text{pr}(A,B) = \text{pr}(A)\text{pr}(B)$

## STATISTICAL INDEPENDENCE

- ▶ Two events **A** and **B** are independent if the probability of **A** occurring does not depend on whether **B** has occurred, and vice-versa
- ▶ If **A** and **B** are independent:
  - ▶  $\text{pr}(A, B) = \text{pr}(A)\text{pr}(B)$
- ▶ If a vector **y** is i.id., then all y's are independent, and

$$y_i \sim \mathbb{D}(\cdot)$$

- ▶ **y** is a random variable drawn from a statistical distribution (more later)

$$A \cup B \text{ (A or B)} = \text{pr}(A) + \text{pr}(B) - \text{pr}(A, B)$$

Partitioning:

$$\text{pr}(A) = \text{pr}(A_1 \cup A_2 \cup A_3 \cup A_4 \cup A_5) = \text{pr}(A_1) + \text{pr}(A_2) + \text{pr}(A_3) + \text{pr}(A_4) + \text{pr}(A_5)$$

If the **A** encompasses all possibilities, then  $\text{pr}(A) = 1$

# CONDITIONAL PROBABILITY

- ▶  $\text{pr}(\mathbf{A} \mid \mathbf{B})$  is the probability that A occurs if B has already occurred.
- ▶ The **joint** probability of two events is equal to the product of their **conditional** probability and the **marginal** probability of the conditioning event (product rule)
  - ▶  $\text{pr}(\mathbf{A}, \mathbf{B}) = \text{pr}(\mathbf{A} \mid \mathbf{B})\text{pr}(\mathbf{B})$
- ▶ If **A** and **B** are independent, then  $\text{pr}(\mathbf{A} \mid \mathbf{B}) = \text{pr}(\mathbf{A})$

## CONDITIONAL PROBABILITY PRACTICE

- ▶ Will you become a zombie?
  - ▶ Assume 0.1% of people are infected but don't know it yet
  - ▶ We have a test that has a 0.5% false negative rate (test is negative when you are infected) and a 1% false positive rate (test is positive when you are not a zombie)
- ▶ You take the test, and the result is positive. What is the probability that you are actually a zombie?

## ZOMBIE?

- ▶ 0.1% infected
- ▶ 1% false positive:  $Z(-)T(+)$
- ▶ 0.5% false negative:  $Z(+)T(-)$

$Z(+)$ $T(+)$	$Z(+)$ $T(-)$
$Z(-)$ $T(+)$	$Z(-)$ $T(-)$

## ZOMBIE?

- ▶ We want the probability of zombiness given a positive test:
  - ▶  $\text{pr}(\mathbf{Z} \mid \mathbf{T})$
- ▶  $\text{pr}(\mathbf{Z}) = 0.001$
- ▶  $\text{pr}(\mathbf{Z}, !\mathbf{T}) = \text{pr}(!\mathbf{T} \mid \mathbf{Z})\text{pr}(\mathbf{Z}) = 0.005 * 0.001 = 0.0000005$
- ▶  $\text{pr}(\mathbf{Z}, \mathbf{T}) = \text{pr}(\mathbf{Z}) - \text{pr}(\mathbf{Z}, !\mathbf{T}) = 0.001 - 0.0000005 = 0.0009995$
- ▶  $\text{pr}(!\mathbf{Z}, \mathbf{T}) = [1 - \text{pr}(\mathbf{Z})][\text{pr}(\mathbf{T} \mid !\mathbf{Z})] = 0.999 * 0.01 = 0.009999$
- ▶  $\text{pr}(!\mathbf{Z}, !\mathbf{T}) = 1 - \text{pr}(!\mathbf{Z}, \mathbf{T}) = 0.990001$

		Z(+) T(+)	Z(+) T(-)
Z(-) T(+)	Z(-) T(-)		
Z(-) T(-)			

YOU ARE PROBABLY NOT A ZOMBIE

- ▶ In a population of 1,000,000 people:
  - ▶ 1000 are zombies...

Z(+) T(+)		Z(+) T(-)
Z(-) T(+)	Z(-) T(-)	

YOU ARE PROBABLY NOT A ZOMBIE

- ▶ In a population of 1,000,000 people:
  - ▶ 1000 are zombies...
  - ▶ of which 995 will test positive

Z(+) T(+)		Z(+) T(-)
Z(-) T(+)		
	Z(-) T(-)	

YOU ARE PROBABLY NOT A ZOMBIE

- ▶ In a population of 1,000,000 people:
  - ▶ 1,000 are zombies...
  - ▶ of which 995 will test positive
  - ▶ 999,000 are not zombies, of which 9,990 will test positive

	Z(+) T(+)	Z(+) T(-)
Z(-) T(+)		

YOU ARE PROBABLY NOT A ZOMBIE

- ▶ In a population of 1,000,000 people:
  - ▶ 1,000 are zombies...
  - ▶ of which 995 will test positive
  - ▶ 999,000 are not zombies, of which 9,990 will test positive
  - ▶ 10,985 will test positive overall

Z(+) T(+)		Z(+) T(-)
Z(-) T(+)		
		Z(-) T(-)

YOU ARE PROBABLY NOT A ZOMBIE

- ▶ In a population of 1,000,000 people:
  - ▶ 1,000 are zombies...
  - ▶ of which 995 will test positive
  - ▶ 999,000 are not zombies, of which 9,990 will test positive
  - ▶ 10,985 will test positive overall
  - ▶ of which 995 are zombies: ~9.1% chance of being a zombie

Z(+) T(+)		Z(+) T(-)
Z(-) T(+)	Z(-) T(-)	

## ANOTHER WAY TO THINK ABOUT THIS

$$pr(Z|T) = ?$$

$$pr(Z, T) = pr(Z|T)pr(T) = pr(T|Z)pr(Z)$$

$$pr(Z|T) = \frac{pr(Z, T)}{pr(T)}$$

$$pr(Z|T) = \frac{pr(T|Z)pr(Z)}{pr(T, Z) + pr(T, !Z)}$$

## ANOTHER WAY TO THINK ABOUT THIS

$$pr(Z|T) = \frac{pr(T|Z)pr(Z)}{pr(T, Z) + pr(T, !Z)}$$

$$pr(Z|T) = \frac{pr(T|Z)pr(Z)}{pr(T|Z)pr(Z) + pr(T, !Z)(1 - pr(Z))}$$

$$pr(Z|T) = \frac{(1 - 0.005) \times 0.001}{0.995 \times 0.001 + 0.01 \times 0.999} = 0.091$$

## CHAIN RULE

$$pr(A, B) = pr(A|B)pr(B)$$

This generalises to:

$$pr\left(\bigcap_{i=1..n} E_i\right) = pr\left(E_n \bigcap_{i=1..n-1} E_i\right) * pr\left(\bigcap_{i=1..n-1} E_i\right)$$

# SO OUR TEST ISN'T GOOD ENOUGH

- ▶ Solution: Make more zombies
- ▶ If  $\text{pr}(\mathbf{Z}) = 0.3$ , and we draw one person at random, we have two outcomes:
  - ▶ **zombie** (30% chance), or **not a zombie** (70% chance)
- ▶ Trivially, if we do this 100 times, we expect the results to look like this:

### DRAW 2 PEOPLE

- ▶ We now have 3 outcomes: 0, 1, or 2 zombies
- ▶ If the draws are independent
  - ▶  $[0] = (1 - [Z])(1 - [Z]) = 0.49$
  - ▶  $[1] = 2[Z](1 - [Z]) = 0.42$
  - ▶  $[2] = [Z][Z] = 0.09$
- ▶ This is a **probability distribution** - literally the distributions of total probability (=1) over the possible outcomes

### GENERALISING

- ▶ If we take **n** draws with probability of the event (e.g., being a zombie) **p**, can we compute the probability of **k** events?

$$pr(k|n, p) = f(n, p) = \binom{n}{k} p^k (1 - p)^{n-k}$$

$$\binom{n}{k} = \frac{n!}{k!(n-k)!}$$

- ▶ This is the **probability mass function (PMF)** of the **binomial distribution**

### PMF, PDF, CDF

- ▶ A **probability mass function** (discrete distributions) or **probability density function** (continuous distributions)  **$f(\mathbf{x})$**  with parameters  **$\mathbf{x}$** :

- ▶ is defined on an interval  $[a, b]$  (may be infinite)

- ▶ is positive

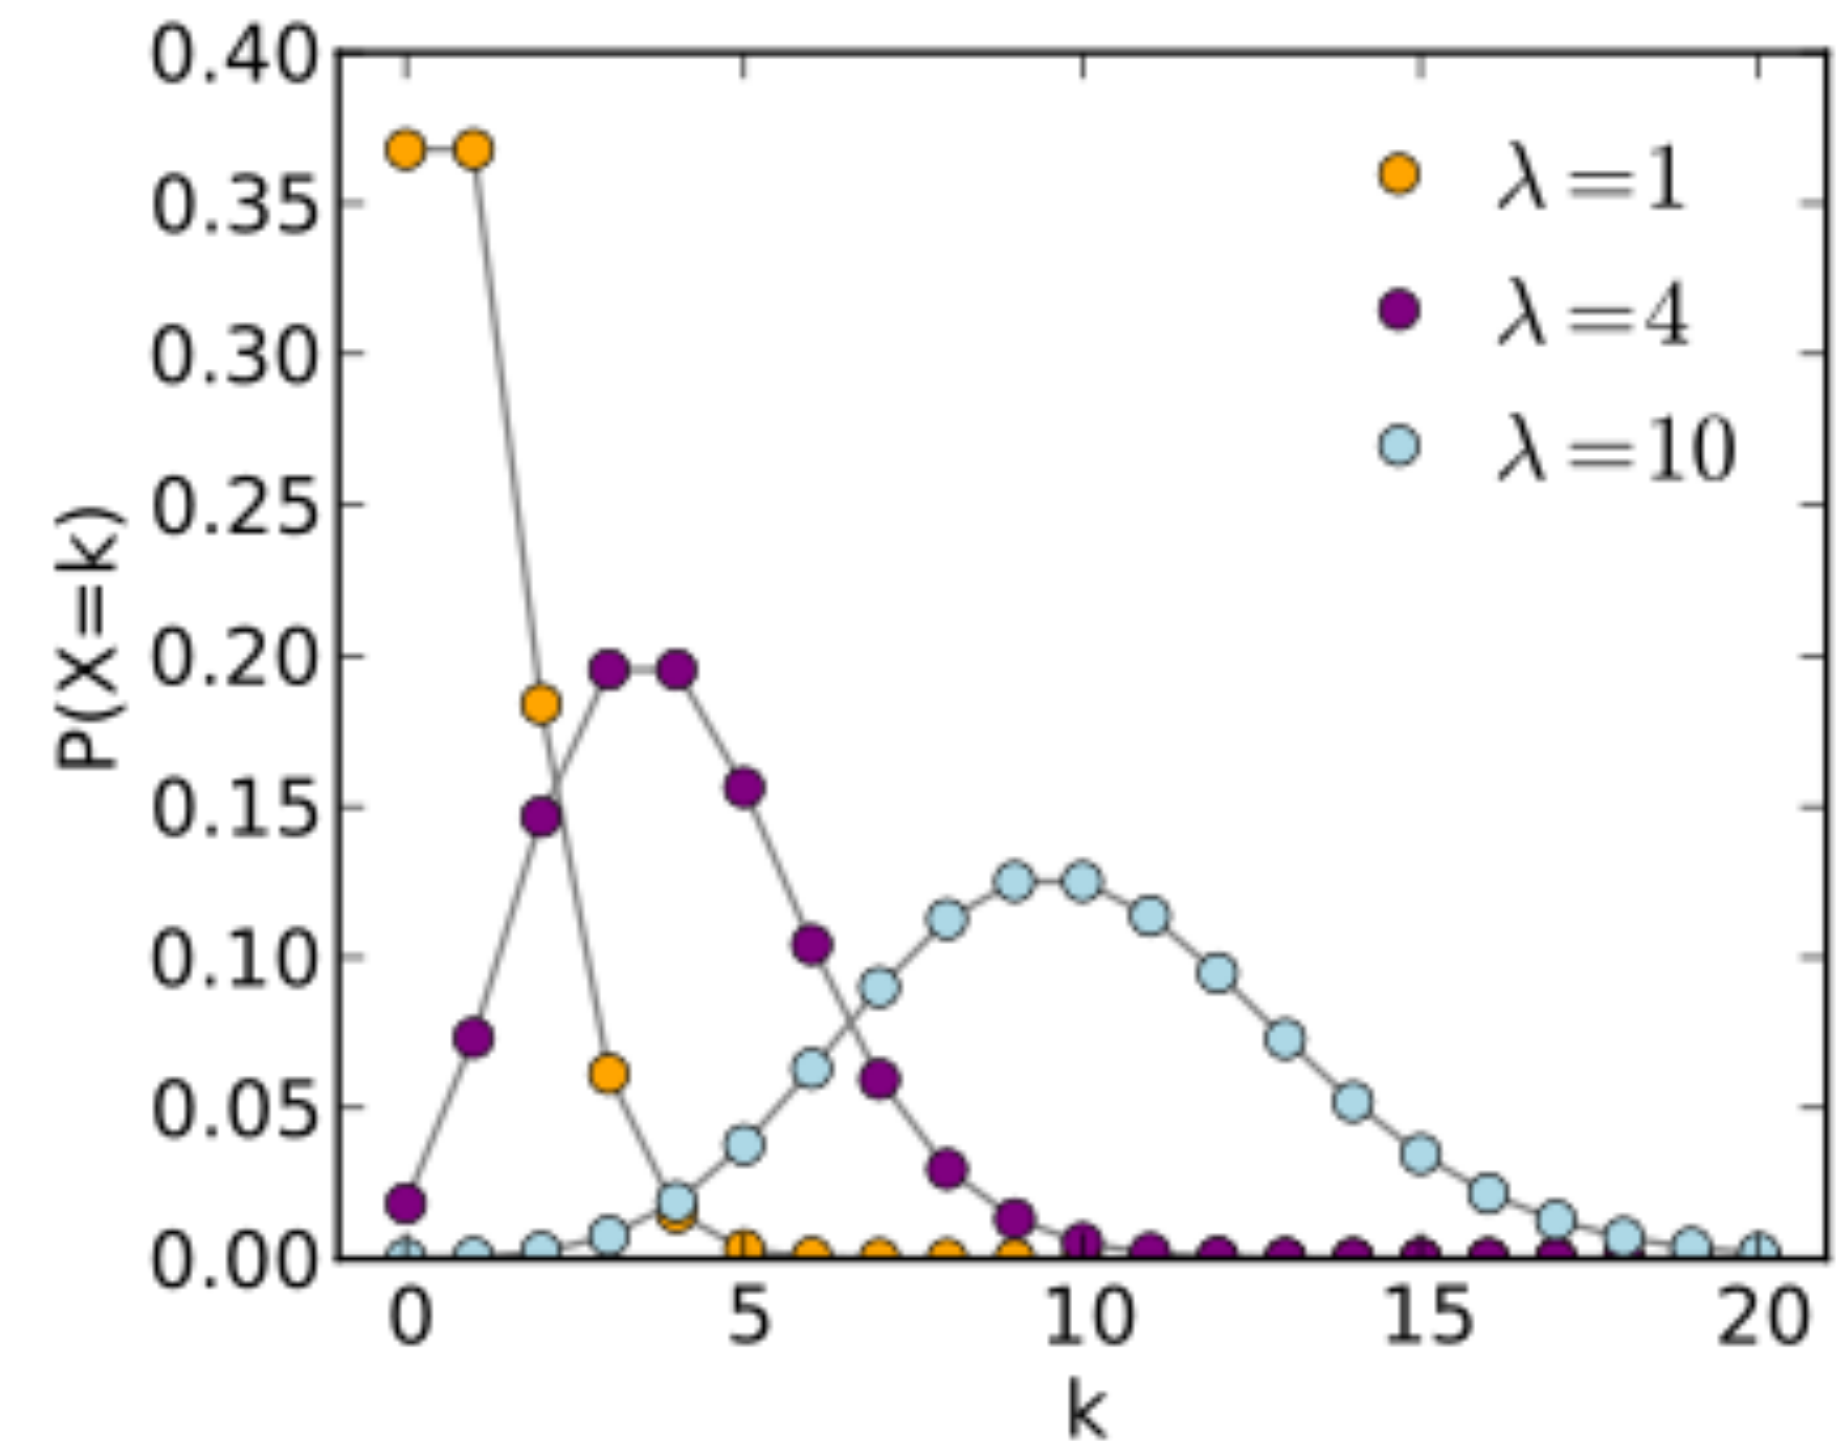

- ▶ is regular (one value for  $f$  for each value of  $x$ , finite derivative), and:

$$\int_a^b f(x)dx = 1$$

- ▶ For every PDF there is a corresponding **cumulative density function**  $g(x,i)$  describing the probability of a value between  $a$  and  $i$

## DISCRETE DISTRIBUTIONS

- ▶ Binomial:  $f(n,p)$
- ▶ Poisson:  $f(\lambda)$

## CONTINUOUS DISTRIBUTIONS

- ▶ Normal:  $f(\mu, \sigma)$
- ▶ Exponential:  $f(\lambda)$
- ▶ Gamma:  $f(k, \theta)$
- ▶ Beta:  $f(\alpha, \beta)$

# DISTRIBUTIONS IN R

- ▶ R has families of distributions:
  - ▶ binom, pois, norm, exp, gamma, beta
- ▶ And functions for each:
  - ▶ probability **d**ensity, cumulative **p**robability, **q**uantiles, and **r**andom draws
- ▶ `dbinom(3, 10, 0.1)` will return the probability of getting exactly 3 events ("successes") in 10 trials with a probability of 0.1

# R PRACTICE

- ▶ What is the probability of observing exactly 6 events in a minute for a poisson process with  $\lambda = 3.6$  events/minute
- ▶ What about for observing **6 or more** events?
- ▶ Is a **probability density** the same as a **probability**?
  - ▶ What is the maximum probability density of a normal distribution with  $\text{mean}=0$  and  $\text{sd}=0.1$ , and at what value (**x**) does this occur?
  - ▶ If it's not the same, what is the probability of observing **x**?
  - ▶ Do these answers make sense? How?
  - ▶ What is the probability of observing a value of  **$x \pm 0.02$** ?
- ▶ For the same normal distribution, find the value **x** such that the probability of observing **x or less** is 0.4. What is **x** if the probability of observing **greater than x** is 0.4?

# A MORE NATURAL WAY TO THINK ABOUT STATISTICS

- ▶ I want to describe some phenomenon ("model")
- ▶ I have some general ("prior") knowledge about the question
- ▶ I gather additional knowledge ("data")

What is the probability that my **model is correct** given what I **already know about it** and **what I've learned**?

# BAYES' THEOREM

- ▶ We really want  $\text{pr}(\text{model} \mid \text{data})$ ; call  $\text{model} = \theta$  and  $\text{data} = X$
- ▶ From the product rule, we know that:

$$\text{pr}(\theta \mid X) = \frac{\text{pr}(\theta, X)}{\text{pr}(X)}$$

$$\text{pr}(\theta \mid X) = \frac{\text{pr}(X \mid \theta) \text{pr}(\theta)}{\text{pr}(X)}$$

$$\text{pr}(Z \mid T) = \frac{\text{pr}(T \mid Z) \text{pr}(Z)}{\text{pr}(T, Z) + \text{pr}(T, !Z)}$$

# BAYES' THEOREM

$$\begin{array}{c} \text{posterior} \\ \text{probability} \end{array} \quad \begin{array}{cc} \text{likelihood} & \text{prior probability} \end{array} \quad \begin{array}{c} pr(\theta|X) = \frac{pr(X|\theta)pr(\theta)}{pr(X)} \\ \text{normalising constant} \end{array}$$

For Bayesian inference, each of these terms is actually a **probability distribution**

### BAYES' THEOREM

$$pr(Z|T) = \frac{pr(T|Z)pr(Z)}{pr(T, Z) + pr(T, !Z)}$$

- ▶ How to evaluate  $pr(X)$ ?
- ▶ For the zombie example, we added up all the different ways one could test positive
- ▶ How to do this for a continuous PDF?

$$pr(\theta|X) = \frac{pr(X|\theta)pr(\theta)}{\int pr(X|\theta)pr(\theta)d\theta}$$

- ▶ This is a hard problem, we will come back to it
